This study was conducted under a grant to Keeping Maine’s Forests (KMF) from the Sustainable Forestry Initiative, Inc.’s Conservation and Community Partnership Grants program, with additional funding from the Horizon Foundation. Alison Truesdale, KMF Coordinator, was the principal author and conducted the survey of Maine SFI participants. However, the study’s Advisory Panel was instrumental in insuring the accuracy and balance of the paper; KMF is grateful for their expertise, time and contributions.

The Sustainable Forestry Initiative® (SFI) is an independent, non-profit organization dedicated to promoting forest sustainability and supporting the linkage between sustainable forests and communities through grant programs, carefully targeted research, direct leadership of critical initiatives, and partnerships that effectively contribute to multiple conservation objectives. Forests certified to the SFI Forest Management Standard cover more than 280 million acres, including over 6 million acres in Maine. SFI’s Forest Management, Fiber Sourcing and Chain of Custody Standards work to ensure the health and future of forests. Through application of these certification standards, SFI’s on-product labels help consumers make responsible purchasing decisions. SFI Inc. is governed by a three-chamber board of directors representing environmental, social and economic sectors equally.

Alison Truesdale; Coordinator, Keeping Maine’s Forests

Alison Truesdale is the sole proprietor of LandForms, providing staffing and consulting services to public, private and non-profit organizations. She is currently serving as Coordinator for Keeping Maine’s Forests and author of *Sustainable Forestry Initiative Certification and Carbon Markets – Opportunities and Barriers for SFI Program Participants in Maine*.

After graduating from Vassar College in 1981 with a BA in Philosophy, Alison returned to Maine. She began working in land use planning in 1989 as a cartographer, researcher, and writer. Over the years, she has written or edited several BMP manuals for state agencies; conducted research on development trends in Maine’s unorganized territory and wildfire risk in the northern Rockies; written successful applications to the Land for Maine’s Future Program; and conducted research and analysis for the Moosehead Lake Region Concept Plan rezoning petition.

Other than development and conservation issues, Alison has pursued an interest in energy efficiency and renewables. She was a certified energy auditor and served on the Energy Savers Committee in her hometown of Yarmouth, reducing the town’s carbon footprint.

Advisors

Mark Berry, M.S.; President and CEO, Schoodic Institute

Mark leads Schoodic Institute at Acadia National Park, a nonprofit dedicated to advancing ecosystem science and learning for all ages. From its Acadia National Park campus, the Institute engages scientists, educators, students, and the public in research and learning. Schoodic Institute’s programs build understanding and appreciation for science and the natural world and contribute to addressing complex challenges in a changing environment. Mark holds a Master’s of Science degree in Ecology and Evolutionary Biology from the University of Colorado and a bachelor’s degree in Environmental and Evolutionary Biology from Dartmouth College. He formerly served as Executive Director of Downeast Lakes Land Trust, where he led landscape scale forest conservation projects, managed a 34,000-acre Community Forest, and implemented one of the nation’s first carbon offset projects.

Ivan Fernandez, Professor in the School of Forest Resources, Climate Change Institute, and School of Food and Agriculture at the University of Maine

Ivan J. Fernandez is Professor in the School of Forest Resources, Climate Change Institute, and School of Food and Agriculture at the University of Maine. He was made a Distinguished Maine Professor in 2007, CASE/Carnegie in Washington DC named him Professor of the Year for Maine in 2008, and was named a fellow in the Soil Science Society of America in 2010 among other awards. He has served on U.S. Environmental Protection Agency Science Advisory Board committees in Washington DC since 2000, he currently chairs a panel of the EPA Clean Air Scientific Advisory Committee (CASAC) that is evaluating the secondary National Ambient Air Quality Standards in the Clean Air Act for sulfur and nitrogen oxides, he represents the University of Maine in the USDA Northeast Climate Hub, and has been involved in leading the Maine's Climate Future assessments in 2009 and 2015. He is a soil scientist by training, with a research program that focuses on the biogeochemistry of ecosystems in a changing physical and chemical climate.

Sherry Huber, Maine TREE Foundation and KMF Steering Committee member

Sherry is a founder of Keeping Maine's Forests and serves on the Steering Committee. She is the former Executive Director of the Maine Waste Management Agency, served in the Maine House of Representatives for six years, and is a Corporator of Maine Health. Sherry chaired the board of Mainewatch Institute and is a former trustee of the College of the Atlantic. She is a former director of The Nature Conservancy, the Land Trust Alliance and NatureServe and currently serves on the Council of Advisors of the last two. She is a former President and current member of the Forest Society of Maine and a member of the University of Maine School of Law Board of Visitors, the Leadership Council of the Yale School of Forestry and Environmental Studies and Maine Conservation Voters. She is an Advisory Trustee of the Maine Audubon Society and an Honorary Director of the Friends of Casco Bay.

George Jacobsen, Ph.D.; Climate Change Institute, Maine State Climatologist and Professor Emeritus at the University of Maine

George L. Jacobson is Professor Emeritus of Biology, Ecology, and Climate Change at the University of Maine. Since his arrival in Maine in 1979, Dr. Jacobson has been a member of the Climate Change Institute, and was Director of the Institute for nearly a decade. His scientific research has focused on long-term climate variability and specifically on forest responses to climate changes during the past 60,000 years. Prof. Jacobson's projects have included sites in North America, South America, and Europe. Among other things, he has served as an outside advisor on climate to the European Science Foundation, and to the Finnish Academy of Sciences. From 2008 to 2014, he had the honorary designation of Maine State Climatologist.

Professor Jacobson joined the faculty of the University of Maine in 1979 after three years working in the United States Senate in Washington, D.C., first as a AAAS Congressional Science Fellow and then as a staff scientist for the U.S. Senate Committee on Environment and Public Works. He was born and raised in Rapid City, South Dakota, and earned a B.A. in 1968 from Carleton College, and a Ph.D. in 1975 from the University of Minnesota. From 1968-1970 he served as a medical specialist in the United States Army.

Dylan Jenkins, M.S.; Vice President of Portfolio Development, Finite Carbon

For over 20 years, Dylan has worked with America's private forest landowners to make sustainable forestry a more feasible proposition. Dylan is currently vice-president of portfolio development for Finite Carbon and leads their sales, marketing, and client relations activity. Before focusing on forest carbon markets, Dylan directed The Nature Conservancy's Forest Conservation Program in Pennsylvania where he developed TNC's Working Woodlands program, and earlier directed the Virginia Forest Landowner Education Program at Virginia

Tech. He was the 2006 SAF National Young Forester of the Year, served as the Virginia SAF chair, was a member of the SAF National Committee on Forest Policy, and co-chaired the SAF Certification Review Board. Dylan has been published in Science, the Journal of Forestry, the Journal of Forest Economics, Forest Landowner, and the ACF Consultant. He is a member of the Association of Consulting Foresters, is an SAF Certified Forester and has a B.S. in Forest Management from Clemson and an M.S. in Forest Economics from Virginia Tech.

Kenneth M. Laustsen, M.F.; Biometrician, Maine Forest Service

Ken has been the Biometrician for the Forest Health and Monitoring Division of the Bureau of Forestry since 1999. Previously, he was Woodlands Analyst, Operations Forester, and staff forester for Great Northern Paper Company in Millinocket (1979-1999).

He has been a member of the Society of American Foresters since 1974, was named an SAF Fellow in 2008, served as an SAF Forest Technology School Accreditation Committee member from 2013 to 2016, and as an SAF Certification Review Board Committee member from 2007 to 2012.

Ken won the United States Forest Service Director's Award for Excellence in 2001. He has been a Member of the USDA Forest Service, Forest Inventory & Analysis, Techniques Research Band since 2008, and a was a member of the Statistics Band from 2002 to 2007. Ken earned a B.S. in Forest Management in 1974 and an M.F. in Forest Management in 2010, both from the University of Maine.

John McNulty, President and CEO, Seven Islands Land Company

John McNulty is President and CEO of Seven Islands Land Company and its subsidiaries based in Bangor, Maine. Seven Islands manages 815,000 acres of forestland for the Pingree family and an additional 350,000 of investor owned timberland through Seven Islands' subsidiary Orion Timberlands. All the lands under management are certified by SFI and the Pingree ownership is dual certified by SFI and Forest Stewardship Council (FSC). Seven Islands' owns and operates a hardwood sawmill, a chipping facility and a hardwood flooring company all located in northern Maine.

John started his career with Seven Islands in 1978 and was named President in 2008. He has been active in the certification arena, both FSC and SFI since 1994 when John was project leader for the Pingree family lands certification, which were the first certified large landholdings under the FSC standard. John has served on the Northeast Standards Committee, several national FSC working groups and has been a vocal advocate of certification since its inception.

John has been active in forestry circles in Maine and nationally, having served on Maine's licensing board and the Society of American Foresters, holding many elected offices in New England as well as representing New England and NY as District Representative on SAF's National Council. He earned his B.S. in forest management from the University of Maine in 1978 and is a licensed forester in Maine.

David Publicover, D.F., Senior Staff Scientist/Assistant Director of Research, Appalachian Mountain Club

Dr. David Publicover is a Senior Staff Scientist and Assistant Director of Research at the Appalachian Mountain Club, where he has worked since 1992. His primary responsibility is to provide scientific information and analyses in support of AMC's mission in forest ecology and management. He oversees AMC's conservation GIS program which conducts regional landscape assessments to evaluate conservation opportunities and priorities, as well as the impacts of specific development proposals. He has served on numerous public policy committees and working groups in the areas of sustainable forestry, ecological reserve design and management and energy facility siting. He oversees forest management planning and FSC certification on AMC's 75,000 acres of forest

land in Maine and led the development of a Climate Action Reserve forest carbon offset project on a portion of these lands. Dave holds a BS (Forestry) from the University of New Hampshire, an MS (Botany) from the University of Vermont and a DF (Forest Ecology) from the Yale School of Forestry and Environmental Studies.

Tom Rumpf, M.F.; former Conservation Strategy Advisor of The Nature Conservancy in Maine and KMF Steering Committee chair

Tom Rumpf is the former Conservation Strategy Advisor for The Nature Conservancy in Maine, where he worked in several capacities over the last 21 years, including as Stewardship Director, Director of Land Protection and Associate State Director. Tom has been project lead for TNC in all the major north woods land conservation projects over the last 18 years, starting with the St. John River acquisition, and most recently with the East Branch, Penobscot River Project. He has had a hand in the conservation of nearly one million acres of lands in Maine. Tom has worked with other TNC staff to explore the feasibility of enrolling TNC lands in Maine in a carbon offsets program. He started his career in Maine, spending nine years with the Maine Forest Service in the policy and program management arena. Tom graduated from the University of Massachusetts with a BS in Forest Management, and holds a Master of Forestry degree from Yale University.

Patrick Sirois, Director of the Maine Sustainable Forestry Initiative

Pat has served as Maine's SFI director since 1997. He represents the third generation of his family's sawmill and logging business in the midcoast area and was a logging contractor for eighteen years.

Executive Summary

Maine's Implementation Committee of the Sustainable Forestry Initiative (SFI) has collaborated with Keeping Maine's Forests (KMF) to study Maine's SFI-certified landowners' participation in carbon credit programs. Forestlands must be certified as sustainably managed to be eligible for the California carbon credit market, and millions of acres of Maine's commercial forest lands are enrolled in the SFI program, yet none have enrolled in potentially lucrative carbon credit programs. The KMF study enlists the expertise of a panel of advisors from the University of Maine's Climate Change Institute, Maine land managers and forestry experts, and a professional carbon project developer to find out why.

California has the dominant cap-and-trade carbon credit market in North America, paying the highest prices for forestry projects that offset carbon emissions from the state's industries. Quebec has linked their program with California's so that Canadian landowners can obtain credits in the California market, and Ontario is in the process of doing the same. While the Regional Greenhouse Gas Initiative (RGGI, covering the New England states, Delaware, Maryland and New York) has the regulations in place to accept forestry offsets projects and has adopted California's forest offset protocols, so far, no one has sought carbon credits for forestry projects in the RGGI market and so no price for forestry offset credits has been established.

To date, the California Air Resources Board (ARB) has issued approximately 57 million offset credits, with 65% of these issued for so-called "improved forest management (IFM) projects". From 2013-2020, as many as 200 million total offset credits have been or may be demanded by California industries to meet their greenhouse gas emission caps. Assuming forestry continues to account for the same percentage of issued offset credits; almost 93 million credits may be in demand from forestry projects between now and 2020. Current offset prices are around \$10 per credit, with projections in the low to mid-teens by 2020. Even if the price stays at today's \$10 per ton, all registered forestry offset projects between now and 2020 are potentially worth nearly one billion dollars.

KMF surveyed Maine's nine SFI Program Participants to find out whether land managers had looked into obtaining carbon credits, and if so, what factors had weighed in their decision to move forward or not. Of the seven survey respondents, all of them had carefully considered getting carbon credits through the California market, but had decided against it, at least for now. While the up-front payout from carbon credits can be substantial and a good way to diversify income from forest land, the land managers found that costs, risks, and the 100-year commitment required by carbon projects not worthwhile at current credit prices.

IFM project carbon stocks are measured against a baseline — the average carbon stocking in the ecological region in which the project lies. Credits are issued for carbon stocking above this baseline and, if the landowner wishes, for future tree growth. Projects are required to maintain a stable or increasing level of carbon. To document, verify and track this carbon, the ARB has rigorous standards for measurement, modeling, inventories, and verification audits. While SFI Program Participants have the advantage of having the staff, software, record keeping and systems in place for designing and maintaining a carbon project over 100 years, the auditing processes for SFI certification and carbon project verification are not similar, so these processes represent additional costs for landowners. Landowners are at risk of having to pay back credits, sometimes with an additional penalty, if the land's carbon stocks decline due to harvests.

Sixteen to nineteen percent of a project's credits are automatically transferred into an insurance pool which fully covers carbon losses due to unintentional declines in carbon stocks from weather events; wildfire; and insect, disease, and pathogen outbreaks. It is not clear; however, whether presalvage harvests related to

spruce budworm infestation would be covered. Indeed, presalvage harvests may require landowners to surrender credits and possibly incur penalties. Given that landowners in Maine can expect two to three spruce budworm outbreaks over the course of a 100-year project, this lack of regulatory clarity represents a substantial risk to current and potential carbon program participants.

The ARB regulations are in effect until 2020 and allow regulated entities to obtain offset credits through November 1, 2021. While the California legislature has committed to a further reduction of statewide greenhouse gas emissions to 2030, the cap-and-trade and offset programs have not yet been renewed and the program's continuation is still being debated. There may be opportunities to influence Quebec and Ontario's GHG reduction programs to facilitate SFI certificate holder participation. Other Canadian Provinces such as New Brunswick and Nova Scotia are also now considering the adoption of market-based greenhouse gas emission reduction regulations and programs. In the meantime, carbon credits are a viable option for landowners whose forestland portfolios have areas with high carbon stocking that can be maintained over the long term. Higher credit prices or poor wood markets could also tip the balance of considerations in favor of improved forestry management projects.

Introduction

Maine has 17.6 million acres of forests, 17.1 million acres (97%) of which is considered timberland. Maine forest landowners are growing more wood than they harvest, and the carbon in the state's forests has increased in volume by almost 5% from 2004 to 2012.¹ Over eight million acres in Maine is managed according to the sustainability standards of the Sustainable Forestry Initiative, Inc. (SFI), and/or the Forest Stewardship Council (FSC), or the American Tree Farm System (ATFS) — a key eligibility criterion for carbon credit programs. Yet, none of the 6.3 million acres of SFI-certified lands in Maine are enrolled in a carbon credit program — not for lack of interest, because all of Maine's SFI Program Participants have considered carbon credits. Maine landowners who participate in other certification programs or adhere to a sustainable long-term management plan approved by a state or federal agency have enrolled tens of thousands of acres in carbon agreements worth millions of dollars.

This paper examines the degree to which forests managed to the Sustainable Forestry Initiative's (SFI) standards in Maine are enrolled in carbon credit programs; analyzes the opportunities and constraints these programs represent for landowners; and examines the strengths and weaknesses of different landowner types when considering enrolling land in a carbon credit program. The study examines the value that sustainability certification adds to the process of obtaining carbon credits, and how changes to the protocol for obtaining carbon credits might enhance the incentives to enroll land.

This study does not address questions about the efficacy of the carbon programs in achieving greenhouse gas reductions or in permanently sequestering carbon in Maine forests. Rather, it examines how carbon credit programs, in fact, function in Maine, regardless of the programs' goals or intentions. The study's survey of SFI Program Participants in Maine, as well as an examination of the carbon projects in Maine that *have* earned credits for landowners, reveals that a variety of constraints prevent some landowners from entering the carbon market. Some constraints are imposed by the program regulations, others by the forest landowner's institutional organization and culture. Consequently, the findings of this paper are specific to Maine. Their applicability to similar forest types or forest landowner types elsewhere should be examined carefully, and on a case-by-case basis.

The carbon credit market is a relatively new economic model; one that has been refined since its inception in 2006 by California's Assembly Bill 32, and is undergoing revision as this paper is written. The California Air Resources Board's cap-and-trade program was the first carbon credit program, and due to the state's status as the world's eighth largest economy, remains the dominant one. Other programs are aligning with California's even as they create their own market.

In 2016, the California legislature passed a bill to extend the state's targeted greenhouse gas (GHG) emission reduction goal to 2030. While the existing program rules were designed to reduce California's emissions to 1990 levels by 2020, the new rules will aim to reduce emissions to 40% below 1990 levels. It is not now known whether the new rules will affect the incentives for Maine landowners to enroll their land in carbon credit programs, but AB 32's codified process for revision allows for this possibility, and it is hoped that this paper might inform that process. In the meantime, it is the goal of this paper to apprise Maine land owners and managers about the opportunities and risks inherent in enrolling land in a carbon credit project.

¹ The Economic Importance of Maine's Forest-Based Economy, North East State Foresters Association; 2013; pp. 3 and 7.

Part I: Carbon Markets

Carbon credit markets have been developed as a means of rewarding those who either reduce their own greenhouse gas (GHG) emissions below regulatory levels, or capture carbon at a rate beyond a “business as usual” scenario, thereby offsetting others’ GHG emissions. Carbon markets can be either regulatory or voluntary.

The voluntary markets have been set up as a way for businesses to demonstrate corporate social responsibility or a higher standard of operation than their industry peers in a non-regulated environment. Voluntary carbon credits are purchased to satisfy personal objectives or corporate standards, and to differentiate a business in the market place as being more sustainable. Voluntary markets were in operation for a decade before the regulatory compliance markets, and served as a testing ground for carbon accounting, verification and pricing.

The regulatory markets have been developed to respond to the carbon emissions goals set by the UN Framework Convention on Climate Change including the Kyoto Protocol.² While there are several regulatory markets (the Regional Greenhouse Gas Initiative (RGGI)³, the Ontario and Quebec carbon markets⁴, and the California market developed and administered by the California Air Resources Board (ARB)), the California market is the largest that allows the use of forestry and forest carbon offset credits, and also commands the highest prices for carbon credits. Maine’s SFI-certified forestland managers who are considering carbon credit programs will be most interested in getting the highest possible price for credits; therefore the discussion below will focus on the ARB standards and processes.

California’s Carbon Credit Market

California’s Assembly Bill 32 (2006) was designed to reduce the state’s overall GHG emissions to 1990 levels by 2020, or 15% lower than the emissions would have been without the regulations. The regulations went into effect in 2013, setting the emissions cap at 2% below 2012 levels. The cap was set another 2% lower for 2014, and then is reduced by 3% each year from 2015 to 2020. Approximately 450 entities that emit 25,000 metric tons of carbon dioxide equivalents (mtCO_{2e}) or more annually are covered, representing 85% of California’s total emissions. These GHGs include not only carbon dioxide, but methane, hydrofluorocarbons, and four other gases.

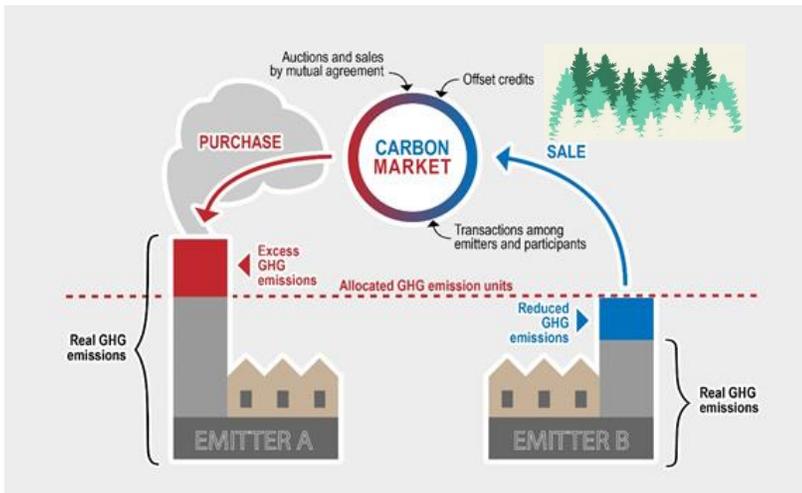

The California program requires *direct* reductions in emissions through energy efficiency improvements, or by generating power from renewable sources rather than from fossil fuels. The annual statewide emissions cap is translated into tradable emission allowances (each allowance typically equivalent to one metric ton of carbon dioxide or carbon dioxide equivalent), which are auctioned or allocated to regulated emitters on a regular basis. At the end of each compliance period, each regulated emitter must surrender enough allowances to cover its actual emissions during the compliance period.

Regulated emitters may also purchase credits for *indirect* emission reductions. Up to 8% of their emissions can

² Even though the US has not ratified the Protocol.

³ The RGGI has adopted California’s forest offset protocol, but has not set a price on offset projects.

⁴ As of 2014, Quebec and California linked their GHG emissions reporting programs. However, because Quebec currently lacks a forest offset protocol, forest offset projects may not be developed in Quebec for use in the Quebec and California’s program. However, forest offset projects developed under the California’s forestry protocol are being used by Quebec entities for compliance purposes in the California market. As of the end of 2016, Ontario was still in the process of developing offset protocols.

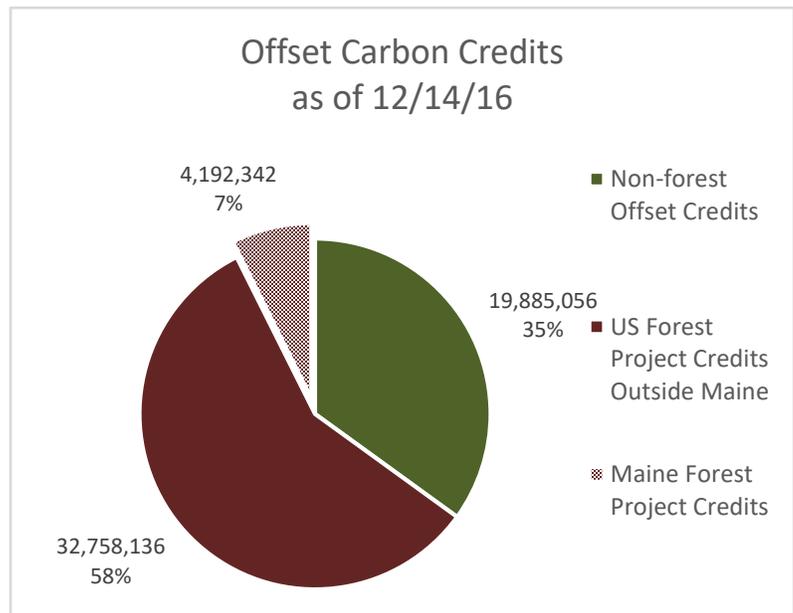

be offset from projects outside capped sectors that are voluntarily engaged in carbon reductions and/or sequestration.⁵ For example, a power plant in California that has not reduced its emissions to the regulatory target level may purchase carbon offset credits from a forest landowner in Maine that has an offset project registered with the ARB, counting the additional carbon sequestered in the forest project area against the power plant’s emissions in order to meet its compliance obligation cap.

As of January 2017, a regulated emitter in California will pay \$50-\$120/ton for pollution control equipment, \$13.57/ton for a California Carbon Allowance (CCA); or \$10+/ton for a California Carbon Offset (CCO). With these price differentials, emitters will maximize the amount of offset credits they can buy each year, ensuring a steady demand for offset credits at least through the end of the 2020.

Carbon Offset Projects

ARB-approved carbon offset projects can be for ozone depleting substances; agricultural methane; urban forestry; mine methane capture; rice cultivation; and US forests. US forest projects, in turn, include reforestation (the reestablishment of forest cover either naturally or artificially); avoided conversion (“preventing the conversion of forestland to a non-forest land use by dedicating the land to continuous forest cover through a qualified conservation easement or transfer to public ownership, excluding transfer to federal ownership”); and improved forest management projects.

To date, the ARB has issued approximately

⁵ The California ARB defines offset credits as “tradeable credits that represent verified greenhouse gas (GHG) emissions reductions or removal enhancements from sources not subject to a compliance obligation in the Cap-and-Trade Program and resulting from one of the following: (1) a project undertaken using an Air Resources Board (ARB or Board) approved Compliance Offset Protocol pursuant to Subarticle 13 of the Cap-and-Trade Regulation; (2) an offset credit issued by a linked jurisdiction pursuant to Subarticle 12 of the Cap-and-Trade Regulation; or (3) a sector-based offset credit issued by an approved sector-based crediting program pursuant to Subarticle 14 of the Cap-and-Trade Regulation.” – California Air Resources Board’s Process for the Review and Approval of Compliance Offset Protocols in Support of the Cap-and-Trade Regulation, May, 2013, p. 1.

57 million offset credits, with 65% of these for improved forest management projects. From 2013-2020, as many as 200 million total offset credits have been or may be demanded by compliance entities to meet their compliance obligations. Assuming forestry continues to account for the same percentage of issued offset credits in the future as in the past, then almost 93 million credits may be in demand from forestry projects between now and 2020. Current offset prices are around \$10 per credit (one credit is equal to one metric ton of sequestered CO₂e), with per credit price projections in the low to mid-teens by 2020. Even if the price stays at today's \$10 per ton, all registered forestry offset projects between now and 2020 are potentially worth nearly one billion dollars.

Offset Project Requirements

To meet the rigorous standards of the ARB market and qualify for credits, all offset projects must demonstrate that the carbon emissions they are reducing are:

1. *Additional*

The climate benefits from the project must be above and beyond the "business as usual" baseline of reductions as defined by the offset protocol. Specifically, the project must sequester carbon stocks that are higher than would be otherwise required by law or regulation, and in the case of forestry projects, higher than the average that occurs on land in the project's surrounding region, with similar growing conditions and under prevalent management practices.

2. *Real, measurable, standardized*

The project must use the best science to rigorously measure carbon and calculate its climate benefits.

3. *Verifiable*

The calculations of the sequestered carbon must be confirmed by an independent third party.

4. *Permanent*

The project reductions must be enduring and functionally equivalent (in the atmosphere) to the emissions the project is offsetting. For forestry projects, "permanent" is defined as 100 years from the date that credits are issued.

The California Air Resources Board has identified three types of forestry projects, each with its own methodology, for meeting the requirements outlined above. The types of forestry projects include:

Reforestation projects which increase removals of CO₂ from the atmosphere through "the restoration of tree cover on land that currently has no, or minimal, tree cover."

Avoided Conversion projects which avert CO₂ emissions by preventing land from being converted from forest to other land uses. Principally, forest land that is demonstrably threatened by development and placed under a qualified permanent conservation easement, or that is transferred to non-federal public ownership within a year of the project commencement date, qualifies as an avoided conversion project.

Improved Forest Management (IFM) projects which involve management activities that maintain or increase carbon stocks on forested land relative to baseline levels of carbon stocks, or "common practice". Common practice statistics for metric tons of carbon equivalent per acre (mtCO₂e/acre) are established by major forest types within supersections (large regions) that have relatively uniform climate, dominant natural vegetation, geology, and soils. The common practice is the average above-ground carbon volume in a project's assessment area (distinct forest community), and is derived from USDA Forest Service's Forest Inventory and Analysis (FIA)

datasets. To determine how much additional carbon is being sequestered by a project, a property's on-site carbon stocks are compared against the common practice statistics for the appropriate assessment area.

Maine is 89% forested, and does not have significant opportunities for reforestation (note that natural regeneration of exiting forests after a harvest is distinct from reforestation). On the other hand, Maine has over 8 million acres of forest certified as sustainably managed. Some of these lands have carbon stocks above ARB's "common practice" benchmark and are eligible for carbon credits as improved forest management projects. Lands that are newly placed under easement could also be eligible as avoided conversion projects. However, because of the substantial eligibility requirements of avoided conversion projects and the high carrying costs of reforestation projects, improved forest management projects are the most significant opportunity for forest landowners, both in Maine and throughout the US.

Process for Obtaining Credits

There is a multi-step process for obtaining credits for improved forest management projects.

Listing

The preliminary step for a project owner (called an Offset Project Operator, or OPO) to receive credits is listing the project on one of three ARB-approved registries: the Climate Action Reserve, Verified Carbon Standard, or American Carbon Registry. Listing a project demonstrates that the registry has verified that the project has met the basic eligibility criteria for offset projects and provides basic information about the project to the public such as who the project operator is, the project's location and size, and the estimated amount of carbon sequestered above and beyond the "common practice" or project baseline.

Listing requires that the OPO establish accounts with both a registry and the ARB, and can be thought of as an application for developing the carbon offset project. It occurs prior to project development (when the project's carbon stocks are inventoried and verified) and all ARB-compliant projects are publicly listed on the registry's website. Listing, by itself, does not guarantee that a project will be developed, or that it will be successfully completed with credits issued. It does, however, establish a project commencement date from which various reporting periods and deadlines are measured; the estimated baseline carbon stocks against which the project, if developed, will be measured; and establishes the applicable protocol under which the project will be developed and monitored.

Project Development

Before issuing carbon credits, the ARB must confirm that the OPO has conducted the initial carbon inventory, growth modeling, monitoring, reporting and verification in accordance with the applicable ARB cap and trade regulation⁶ and current forest protocol⁷. The regulation describes the process for obtaining and trading credits and describes the requirements for measuring, verifying and reporting carbon stocks. The forest protocol prescribes the formulae for calculating carbon stocks and the requirements for managing forests so that a

⁶ This paper's description of the cap and trade regulations are taken from the unofficial electronic version of the Regulation for the California Cap on Greenhouse Gas Emissions and Market-Based Compliance Mechanisms accessed on March 2, 2016 at: https://www.arb.ca.gov/cc/capandtrade/capandtrade/unofficial_ct_030116.pdf. The official regulation can be accessed at:

⁷ The 2015 protocol can be accessed at:

<https://www.arb.ca.gov/cc/capandtrade/protocols/usforest/forestprotocol2015.pdf>.

project area's carbon stocks are maintained over time.

The Carbon Inventory

After project listing, the OPO conducts a carbon inventory for the project area which includes not only merchantable wood, but also the carbon in non-merchantable trees and tree parts. One of the key benefits of carbon credit programs for forest landowners is to be able to monetize portions of trees that are underutilized in conventional forest products. In addition to the carbon in tree and tree components used for conventional wood products, OPOs may be issued credits for the carbon volume in:

- unsound trees,
- stumps, coarse roots, and branches,
- standing dead trees,
- trees without a single straight bole, and trees that are 1.0-4.9" in diameter.

Sample plots within the project area are defined and mapped so that they can be remeasured with accuracy over the 100-year life of the project. All woody biomass (4.5" DBH and larger) within the sample plots must be measured, plots are generally monumented, and each tree is marked with an individual identifier. Accuracy is essential, as the ARB requires a confidence level on the sample of 90%, plus or minus 10%. Designing the sampling process is critical to the success of a project and requires a registered forester with special expertise.

Steps in Calculating Carbon Credits

1. Estimate baseline onsite carbon stocks;
2. Estimate baseline carbon in harvested wood products;
3. Determine actual onsite carbon stocks;
4. Determine actual carbon in harvested wood products;
5. Calculate the forest project's secondary effects; and
6. Determine applicable confidence deductions and discount factors.

The carbon inventoried in a forest offset project includes a portion of the harvested timber. Generally speaking, kiln-dried wood is 50% carbon, so, depending on the ultimate use of the wood, harvests do not cause all the trees' carbon to be lost to the atmosphere. In addition to the carbon in the standing timber, forestry offset projects can be credited for the long-term storage of carbon in long-lasting wood products. On the other hand, the ARB forestry protocol recognizes that harvesting, processing, and transporting wood and wood products necessitates the use of machinery that burns fossil fuels. Projects can also necessitate soil disturbances during site work and cause decomposition of forest materials, both of which result in greenhouse gas emissions.⁸ The protocol includes formulae for calculating these secondary effects of a harvest and requires the reduction of the carbon stocks accordingly.

Modeling

Once the initial carbon stocks are inventoried and verified, the OPO conducts an annual "desktop" audit. This involves estimating the current amount of biomass and growth within the project area and then accounting for planned harvests and the end use of the harvested wood. The annual modelling is done using mill receipts, harvest tallies, ARB-approved biometric equations, and growth and yield software.

The initial inventory and modeling data are submitted to the ARB as an Offset Project Data Report (OPDR). Assuming the project is approved by the ARB, the OPO will submit OPDRs annually for the life of the project.

⁸ Although soil carbon is not a creditable pool under the ARB forest offset protocol.

These reports serve as a mechanism for monitoring the credited carbon over the life of the project and document the growth (or decline) of carbon stocks as new trees take root and existing trees grow and die and/or are removed through scheduled harvests and silvicultural operations. The OPO can request credits for additional growth over and above the initial carbon stocks, with the provision that the timeline for the project is reset for 100 years from the date of the issuance of the new credits.

Reporting

The OPO must submit the first Offset Project Data Report (OPDR), including inventory and modelled projections, within 24 months of listing the project. Thereafter, the OPO submits annual reports based on the remodeled carbon accounting and new inventory, when applicable. Failure to submit a data report is interpreted by the ARB as a voluntary termination of the project.

After the first reporting period, verification must be conducted at least once every six years and may cover up to six reporting periods for which Offset Project Data Reports were submitted. All verification reports must be submitted within 11 months of the reporting period being verified.

Verification

The ARB requires third-party verification on a sample of the inventoried plots. The verification body must be ARB approved, and the offset verification statement (OVS) itself must be reviewed internally by someone not directly involved in the verification process. As a third check for reliability, the ARB reviews the verification statements. Finally, no verification body can issue verification statements for the same project for more than six consecutive reporting periods. After the sixth verification statement, the OPO must rotate to another verification service.

The verification of the initial data report requires a site visit after the report is submitted and must:

- a. Confirm that the offset project is eligible under the ARB protocol and that the project meets the requirements for additionality;
- b. Confirm that the offset project boundary is appropriately defined;
- c. Review the project baseline calculations and modeling;
- d. Assess the project's operations, functionality, and data control systems, and review the techniques for measuring and monitoring GHG; and
- e. Confirm that all eligibility criteria applicable to project design, measurement, chain of custody, and monitoring conform to the Offset Protocol.

Assuming the offset project is approved, the OPO's data reports will then be verified every six years, and inventories every twelve years. If a verification statement is not received within 11 months of the reporting period which the statement has reviewed, the project will not receive any carbon credits for the carbon sequestration documented by the OPDR.

The project development process demands a deep understanding of the forest protocol, how to design a precise sequential sampling regime, and how to strategically optimize forest management plans. While most OPOs will hire professionals to develop an IFM project, not all do. The ongoing inventory, modeling and reporting requirements demand a high level of expertise, staff time and the necessary hard- and software. In this regard, SFI Program Participants are particularly well-suited to developing and maintaining IFM projects.

Registration and Sales

Once a project receives a successful third-party OVS, the registry will then review the project and, if it is in

compliance with the protocol, issue temporary registry offset credits (ROCs) to the project. The project is then handed off from the registry to the ARB for a final review of compliance with the offset regulation and protocol. If the ARB approves the project, the ROCs are cancelled and the ARB issues Air Resource Board Offset credits (ARBOCs) which may be sold by the OPO and used by regulated entities for compliance purposes within the ARB's GHG emissions trading program.

Credits do not have to be sold: they can be “banked” (essentially left on the books in the OPO's account at the ARB), traded for credits in other compatible markets, or sold gradually over time. When credits are sold, the price is negotiated privately between the buyer and seller.

Invalidation Risk, Reversals, and Project Termination

The number and value of the carbon credits issued to a project take into consideration the risk that a project's stated climate benefits are later found to be invalid; that the carbon stocks may be diminished, either inadvertently or purposefully; and that the project may be terminated. These risks are calculated at the beginning of the project.

Invalidation

If a project, after registration, is found to be fraudulent or its carbon stocks cannot be verified, it is considered invalid. The ARB regulations allow an 8-year window for credits to be found invalid. Credit buyers can demand a price discount to hedge against this risk or require a 3-year invalidation window instead, obtained by getting a second successful independent third-party verification.⁹

Unintentional Reversals

The regulation requires the landowner to replace all “reversed” offsets. Weather events, insect damage and other uncontrollable circumstances can effectively release carbon to the atmosphere. If credits have been issued to a forest offset project for this carbon, it is considered an unintentional reversal. Unintentional reversals are compensated for from a mandatory reversal risk “buffer pool” of credits managed by the ARB. The buffer pool serves as an insurance mechanism for unintentional reversals of any magnitude and on average, approximately 16-20% of a project's initial credits are placed into this buffer account which insures all forestry offset projects. Offset credits deposited into the risk buffer pool have no market value per se, and may not be traded between market participants. The amount contributed to the buffer account may be reduced through the use of a qualified conservation easement that gives the ARB third-part enforcement rights.

As an example, a wildfire that burns part of a project area is an unintentional reversal, releasing a significant portion of the above-ground carbon fixed in the wood to the atmosphere. Other examples of unintentional reversals include those from insect damage or wind storms. Project operators are required to report a reversal within 30 days of its discovery, remeasure the project's carbon stocks within one year of the reversal, and have the new carbon inventory verified by a third party. The later inventory is compared with the previous annual estimate on record for issued credits. The ARB then retires a number of credits from the buffer account equal to the number of tons of CO₂ reversed.

Intentional Reversals

The ARB defines an intentional reversal as “any reversal . . . which is caused by a forest owner's negligence, gross negligence, or willful intent, including harvesting, development, and harm to the area within the offset project

⁹ Both the voluntary and compliance markets also sell premium or “golden” credits for projects with no invalidation risk.

boundary.”¹⁰ The reporting requirements for intentional reversals are the same as for unintentional reversals, but compensation for the lost carbon must be paid for, within 6 months, in credits from the OPO’s account (rather than the buffer account).

Legitimate intentional reversals may occur as a planned part of silvicultural operations (for example to balance age classes or reduce wildfire risk). These are recognized by the ARB, but do not change the requirement to compensate for such reversals. Project owners should retain sufficient unsold credits in their account to compensate for these anticipated reversals.

Project Termination

Whether intentional or unintentional, a major reversal can potentially eliminate all, or even more, of the sequestered carbon for which credits have been issued. When a project’s carbon inventory goes below the baseline carbon stocks at the project’s initiation, the ARB will terminate the project.¹¹ If the reversal was unintentional, the project’s buffer account will cover the reversal, and the OPO must re-inventory the project area to document the project termination.

When an intentional reversal causes the project to terminate, the OPO must pay back the offset credits out of their own account, plus a penalty. The amount of the penalty depends on the duration of the project. It can be between 1 and 1.4 times the number of credits reversed, with newly commenced projects incurring penalties at higher rates (see the table at right).

Penalty Rate for Early Termination Due to Intentional Reversal	
# years between offset project commencement and termination	Compensation Rate
0-5	1.40
>5-10	1.20
>10-20	1.15
>20-25	1.10
>25-50	1.05
>50	1.00

Forest Management

For improved forest management projects, the additionality criterion means the forest protocol represents an extra layer of proscriptions, over and above what is required by state regulations and sustainability certification standards, and beyond the “common practice.” This paper will focus on the forest management requirements in the 2015 *Compliance Offset Protocol: U.S. Forest Projects*, although it should be noted that early forestry offset projects were registered using the previous (2014) protocol.

Eligibility requirements for forest offset projects are as follows:

1. projects must be located within the contiguous 48 states, or specific parts of Alaska;
2. the Offset Project Operator must demonstrate that the forest is sustainably managed; and
3. projects must be managed under a “natural forest management” regime.

The latter two requirements are designed to ensure that projects will be managed so that carbon stocks will be maintained over the course of the project. Forests are considered sustainably managed if they are third party

¹⁰ “A reversal caused by an intentional back burn set by, or at the request of, a local, state, or federal fire protection agency for the purpose of protecting forestlands from an advancing wildfire that began on another property through no negligence, gross negligence, or willful misconduct of the forest owner is not considered an intentional reversal but, rather, an unintentional reversal.” Title 17. Division 3. Chapter 1. Subchapter 10. Article 5. Subarticle 2, § 95802. (190).

¹¹ Projects can also be terminated when the project land or timber rights are sold and the new owner does not wish to be responsible for the project commitments; or the OPO can terminate the project themselves. In these instances, credits must be repaid.

certified under the Sustainable Forestry Initiative, the Forest Stewardship Council, or the American Tree Farm System. Alternatively, lands can be managed under a federal- or state-sanctioned sustainable management plan, or with uneven-aged silvicultural practices with canopy retention averaging at least 40% across all the forestland owned by the Offset Project Operator (whether part of the project area or not).

Natural Forest Management

The “natural forest management” requirement includes the following provisions:

- A project’s standing live tree carbon stocks must consist of at least 95% native species.
- If even-aged management is practiced on a watershed scale up to 10,000 acres (or the project area, whichever is smaller), projects must maintain no more than 40% of their forested acres in ages less than 20 years, and certain harvest size and buffer area requirements must be met.
- Generally, projects must maintain one metric ton of carbon per acre or 1% of standing live tree carbon stocks, whichever is higher, in standing dead tree carbon stocks to diversify the forest structure and provide wildlife habitat.
- Projects must maintain the standing live tree carbon stocks within the project area over any 10 consecutive year period during the project life, except as follows:
 - Any decrease is demonstrably necessary to substantially improve the project area’s resistance to wildfire, insect, and/or disease risks;
 - The decrease is associated with a planned balancing of age classes;
 - The decrease is due to an unintentional reversal; or
 - The decrease in standing live tree carbon stocks occurs after the final crediting period (during the required 100-year monitoring period) and the residual live carbon stocks are maintained at a level that assures all credited standing live tree carbon stocks are permanently maintained.

Forest offset projects must *not*:

- experience a decrease in standing live tree carbon stocks that results in the standing live tree carbon stocks falling below the forest project’s baseline standing live tree carbon stocks (derived from the mtCO₂e/acre for the project’s assessment area) or 20 percent less than the forest project’s standing live tree carbon stocks at the project’s initiation, whichever is higher; nor
- employ broadcast fertilization.

Part II: Results from Survey of Maine SFI Program Participants

Large landowners (with over 10,000 acres) in Maine include families, forest products companies, logging contractors, nonprofit conservation organizations, tribes, real estate investment trusts (REITs), timber investment management organizations (TIMOs), and the public (state and federal government). In general, it should be noted that many of Maine’s large landowners do not manage their own land, but hire forest management companies for this purpose. Consequently, the decision-making body that sets overall financial and management goals differs from the one that makes and executes day-to-day forest management decisions.

There are 8.3 million acres in Maine certified as sustainably managed. Seventy-five percent (6.3 million acres) are SFI-certified. In the summer of 2016, Keeping Maine’s Forests emailed the nine companies that manage these lands a survey regarding their past and future assessments of carbon credit programs. The questions were open-ended so that the survey didn’t predispose the respondents toward specific answers. The questions were as follows:

Acres in Maine Certified as Sustainably Managed by Third Parties as of August 18, 2016	
Certification Program	Acres
SFI and FSC dual certification	3,378,242
SFI only	2,874,277
FSC only	1,680,701
American Tree Farm System	375,000
Total	8,308,220

Survey of SFI Program Participants

1. Have you ever *considered* entering into any carbon credit program?
 - a. Why, or why not? What were your reasons for investigating carbon credit programs (or not)?
2. Have you *pursued* entering into any carbon credit program?
 - a. If yes, what activities did you engage in to explore carbon credit programs (e.g., looked into hiring an expert to evaluate the viability of credits for my land; conducted an analysis of the costs and benefits; reviewed the forestry protocol, etc.)?
 - b. If no, why not?
3. Are you currently engaged in a carbon credit project?
 - a. If so, when was/will your project be listed? On which registry?
 - b. For those who looked into carbon credit programs but decided against pursuing a project, what made you decide not to pursue carbon credits for your land? Please be as specific as you can be.

Seven of the nine surveys were returned. All the respondents had considered a carbon credit project on their lands; some had been looking into the feasibility of a project as long ago as 2008. Most companies had been approached by, or worked with, one or more firms that develop carbon projects. Several land management companies said that they had considered carbon projects several times, or on an ongoing basis. Uniformly, land managers said they considered carbon projects for the potential revenue. Two also responded that they wanted to understand their options with regard to the carbon credit programs.

Land managers are clearly diligent in investigating carbon credit programs. They reported having done analyses of the fiscal impacts of entering into a carbon credit program, they looked at more than one potential carbon

project area, and they consulted with various experts. Some also said that they periodically review the carbon credit program rules and forestry protocol.

Respondents' Reasons for Not Enrolling Land

None of the seven survey respondents had enrolled SFI-certified land into a carbon credit program. Their responses as to why varied in content and detail. Following is a synopsis of all the reasons cited; many of these reasons are closely associated with one another.

Length of Commitment

The time commitment of maintaining and operating a forest offset project for 100 years (or longer, if credits were obtained for growth after the initiation of the project) was a universal concern. Often the length of the commitment was mentioned in conjunction with other concerns – cost, risk, or impact on forest management – as an exacerbating factor.

Risk, Uncertainty

Risk and uncertainty were prominent factors that kept land managers from enrolling land in carbon credit programs. The impact of spruce budworm infestations is one specific concern. Spruce budworm has a natural cycle of 30-40 years, with the potential to affect Maine's forests two or three times over the course of a 100-year carbon project. The next infestation has begun in Quebec and New Brunswick, with early signs of the insect occurring in northern Maine. During the last outbreak in Maine, 20-25 million cords of spruce and fir were killed by the caterpillars, although there is no way to accurately predict the severity of the impending outbreak.

Images of defoliated spruce and fir from Maine (left) and Canada (right) during the 1970s-80s spruce budworm outbreak.

Land managers are, in some cases, using presalvage harvests to remove healthy mature spruce and fir whose needles are the food that the insect feeds on. The hope is that presalvage cuts will reduce the severity of the infestation and that landowners can earn revenue from the trees before they are killed through successive years of defoliation. How such harvests will be treated under a carbon agreement is unclear.

At least one land manager has asked the Air Resources Board to clarify whether presalvage harvests would be considered intentional or unintentional reversals. While the forest protocol allows for planned reversals to balance age classes or where “the decrease is demonstrably necessary to substantially improve the project

area's resistance to wildfire, insect, and/or disease risks",¹² there has not been a clear answer from the ARB as to how they would view presalvage harvests. As IFM projects in general are still a relatively new type of offset credit, this may be because the ARB does not, yet, have an agreed-upon mechanism for determining when a presalvage harvest has been demonstrated to be necessary. In any case, with the prospect of having to either pay back credits for a reversal due to presalvage harvests or allow a substantial volume of spruce and fir to die on the stump and then having to harvest other species to meet wood supply agreements (which would also risk credit repayments for intentional reversals), the decision was not to enter into a carbon credit program at all.

Other perceived risks mentioned by survey respondents included: uncertainty about the accuracy of the required modeling (especially when accounting for Maine tree species' shorter life cycle and the mortality caused by spruce budworm); the adequacy of the buffer pool to cover losses due to windthrow and spruce budworm; and how the long-term encumbrances might be perceived and valued by timberland lenders and buyers. Two survey respondents were concerned that future FIA updates would reduce the additionality on the lands they manage. One cited easements on others' lands that disallow harvesting as a factor that they had no control over, but which would diminish additionality on the lands they manage over time.

Forest Protocol Restrictions

Some provisions of the ARB forest protocol are a concern for Maine's SFI participants – primarily, the regulation of even-age management that restricts clearcutting and shelterwood harvests. In Maine, where the life spans of some common tree species are significantly shorter than in California and spruce budworm infestations must be managed, even-age management is an important management tool for stimulating tree growth. Even-age management also provides early successional wildlife habitat which can help landowners meet sustainability certification standards.

Value of Credits Versus Costs of the Program Over 100 Years

The survey respondents were concerned with the costs of entering into a carbon agreement and maintaining a carbon project. Project development costs (inventory, modeling and project documentation, verification, and offset transactions) vary widely, but are approximately \$150,000 for the smallest offset projects. In addition, landowners must set aside at least \$200,000 to cover long term project maintenance and operations costs over 100 years or more for ongoing modeling, inventories and verifications. If a consultant is needed to conduct a feasibility study, that is a significant, additional cost.

Two other reasons were given by one forest land manager as to why they did not enter into carbon credit programs. First, a substantial portion of the lands they manage are covered by a working forest conservation easement that was purchased using Land for Maine's Future (LMF) bond funds. The easement includes language that has been interpreted as prohibiting lands protected through the LMF program from participating in carbon credit programs. In fact, the current template for working forest easements purchased with LMF bond funds expressly extinguishes the right to use land to mitigate for development elsewhere, "as might otherwise occur in cluster zoning laws, transfer of development rights schemes, and carbon sequestration and carbon dioxide credit programs."¹³ Second, the manager noted that subdivision of land under a carbon agreement is difficult and complicated.

¹² See 3.1(b)(1)(A), pages 21-22 of Compliance Offset Protocol: U.S. Forest Projects; California Environmental Protection Agency Air Resources Board; Adopted June 25, 2015.

¹³ Maine Department of Agriculture, Conservation and Forestry; *Drafting Guidelines for Working Forest Easements Funded by the Land for Maine's Future Program*, adopted by the Land for Maine's Future Board June 25, 2002; page 6-10. The exact

Land managers summed it up by saying that carbon credits were simply not valued highly enough to make carbon programs worthwhile. As one person put it, “where there are good markets for wood, it pays more to grow and harvest that wood.” While higher credit prices will not address all the concerns raised by the survey respondents, they would address cost and, to some extent, risk concerns. One land manager thought that a price of \$20 per carbon credit (roughly double the current price) would be enough to have them enroll land in a program.

Current Carbon Credit Projects in Maine

Despite these barriers to participation in carbon markets, as of December 2016, there have been six projects that have obtained carbon credits in Maine. Clearly, some landowners are finding benefits to entering into carbon agreements.

Carbon Credit Projects in Maine as of December 2016, by Acreage					
Project Name	Ownership Type (OPO)	# Acres	# Offset Credits	Carbon Market	Initial Credits/Acre
Passamaquoddy Tribe	Tribe (Passamaquoddy Tribe)	98,532	3,218,469	CA ARB	33
Lyme Grand Lake Stream	TIMO (GLS Woodlands, LLC)	19,552	599,217	CA ARB	31
Farm Cove Community Forest Project	NGO (Downeast Lakes Land Trust)	19,118	284,043*	CA ARB	13
Katahdin Iron Works Ecological Reserve	NGO (Appalachian Mountain Club)	9,037	123,344	voluntary market	14
Alder Stream Preserve	NGO (Northeast Wilderness Trust)	1,530	36,596**	CA ARB	20
Howland Research Forest	NGO (Northeast Wilderness Trust)	552	54,017***	CA ARB	79
<p>Source: California Air Resources Board: https://www.arb.ca.gov/cc/capandtrade/offsets/issuance/arb_offset_credit_issuance_table.pdf and embedded links to project documentation; and the Climate Action Reserve: https://thereserve2.apx.com/myModule/rpt/myrpt.asp#top, accessed January 11, 2017.</p> <p>* Includes 242,131 credits for carbon stocks at project initiation and 41,912 credits for growth.</p> <p>** Includes 31,290 credits for carbon stocks at project initiation and 5,306 credits for growth.</p> <p>*** Includes 43,687 credits for carbon stocks at project initiation and 5,165 credits for growth.</p>					

Most of Maine’s carbon projects have been initiated by NGOs.¹⁴ Since 75-90% of the income from carbon credit programs comes from the up-front payment for existing carbon stocks, the landowners who will benefit most are those with older growth and less need for timber revenues going forward. The Katahdin Iron Works

language of LMF-funded working forest easements has changed over time; earlier language did not mention carbon credit programs specifically, but has been interpreted to disallow entry into the regulatory market while allowing entry into the voluntary market.

¹⁴ To date, the lands in Maine that have been enrolled in carbon credit projects have been FSC-certified rather than SFI-certified; this is based on only a few projects and appears to be largely a result of a tendency for Maine NGOs to have preferred FSC certification. There is no limitation of the SFI certification program with regard to the potential for enrollment of SFI certified lands in carbon offset projects.

Ecological Reserve, Alder Stream and Howland Research Forest projects are all operated by entities that prohibit all harvesting on these lands. The other projects are operated by entities that do allow harvesting, but presumably are confident they will not risk significant reversals due to harvesting or natural events.

The Lyme Grand Lake Stream project is the only one initiated by a TIMO. With this project, Lyme Timber Company entered into a carbon agreement with the understanding that part of the proceeds would go toward lowering the price of the land for their buyer, Downeast Lakes Land Trust. The trust was able to obtain the forest land at a reduced price, and assumed the operation and maintenance costs of the project. These costs may be somewhat reduced since their Farm Cove Community Forest project is adjacent to the Grand Lake Stream project, and the trust can, perhaps, take advantage of some efficiencies.

There is a wide range of credits earned per acre. Northeastern projects typically earn 10-25 credits per acre at initial issuance. The Passamaquoddy and Howland projects demonstrate that the value of carbon projects increases the longer the forest has been conservatively managed. The Howland Research Forest is dominated by spruce and hemlock stands that average 140 years old, but that's a rare occurrence in Maine where the forests have been managed for 250 years.

Landownership Type and Related Management Goals

The predominance of NGOs in the group of carbon project operators in Maine points to another factor which influences whether and when landowners enter into the carbon market: the legal structure of the landowner and their organizational mission. Each institution has its own legal structure, history and culture that influence its values and tolerance for risk and regulatory oversight. There are some institutional landowners that have made a commitment to offsetting climate change consistent with their organizational mission (e.g., the Appalachian Mountain Club); others have a fiduciary responsibility to provide an income stream to shareholders (e.g., family landowners). These are all important decision-making characteristics that come into play when making a 100-year commitment.

The length of time a landowner plans to hold the land is a factor. TIMOs, REITs and Industrial landowners who are not structurally committed to long-term ownership must factor into their decision-making process that a carbon project may affect the sale price of a piece of land. On the other hand, it can also enable the seller to benefit from the initial credit sale, while leaving the long-term project costs to the new landowner (as with the Lyme Grand Lake Stream project).

Different owner types have different needs in terms of revenue streams. Some owners, such as NGOs, may not require much or any revenue from timber. Others may depend on a steady income from timber revenues and may see the California forestry protocol as potentially conflicting with their needs.

Likewise, family ownerships rely on a steady stream of timber revenues over the long term. Carbon credits may pay off up front, but the long-term costs may mean that the carbon revenues need to be held in escrow for project operation and maintenance costs rather than used for shareholder income, making the project less attractive as a source of revenue.

Incentives for Landowners to enter Carbon Credit Programs

In sum, there is a robust, if short-term; market for carbon credits through 2020 that Maine forest landowners can take advantage of. There are important considerations for each landowner entering into the carbon credit market, and there is no one-size-fits-all approach to deciding whether the costs and risks are worth the tangible and intangible benefits. Despite the deterrents discussed above, there are important incentives for all landowners which include:

Part II: Results from Survey of Maine SFI Program Participants

- Payments for conservative harvests, or no harvesting.
- Revenue from otherwise unmerchantable wood; and
- The opportunity to diversify revenue streams – from harvesting and from carbon.

In addition, some landowners may be able to:

- Capitalize on the expertise, staff and software needed for sustainability certification in order to manage a carbon project over the long-term; and
- Monetize carbon value that exists as a consequence of conservation or preservation practices that are part of the organization's mission or practice, but that would otherwise be unrealized.

Part III: Strengths, Limitations, Opportunities and Constraints of Carbon Credit Programs for SFI Program Participants

The California ARB cap and trade regulations and Improved Forest Management protocol represent both potential opportunities and constraints for forest landowners in Maine who are managing their lands in accordance with forest sustainability certification criteria. There are also strengths and weaknesses in the forest landowners' decision-making processes, along with a culture and history that make them more or less likely to consider entering into carbon credit programs.

Landowner Strengths

Since participation in one of the three sustainability certification programs (through the Sustainable Forestry Initiative, Forest Stewardship Council, or the American Tree Farm programs) is the primary means of satisfying the forest sustainability criterion for eligibility to participate in carbon credit programs, being an SFI Program Participant is an asset for those seeking credits. All the carbon credit programs recognize that sustainable harvests are a prerequisite for maintaining carbon levels in managed forests.

Participation in SFI and other sustainability certification programs have other benefits, however, that are not as obvious. Certification programs have their own programmatic and practical requirements that confer advantages to participants seeking carbon credits. Sustainability certification requires the same centralized organizational, decision-making, record-keeping, and program monitoring structures that are necessary to develop and maintain a carbon credit program. In addition, both certification and carbon offset programs require:

- Sufficient ownership and tree cover to make forest and/or carbon management fiscally feasible;
- Compliance with applicable laws and regulations;
- Natural forest management practices;
- Sustainable harvesting levels;
- Forest monitoring activities;
- Forest inventory data collection;
- Growth and yield projections; and
- Independent third party verification.

These requirements, in turn, necessitate having highly qualified staff who can utilize sophisticated software and sampling and inventory methodologies (or the capacity to manage relationships with consultants that provide these capabilities). The costs and rigor of carbon credit projects mean that landowners who are participants in sustainability programs have a substantial advantage in developing and/or maintaining a carbon project over non-certified landowners. Relative to their certified peers, non-certified landowners that participate in carbon offset projects will likely be more reliant on hiring new staff, training their own staff, and/or contracting with consultants over the 100 years of the carbon project, incurring additional project operations and maintenance costs.

Certification also necessitates that the landowner be willing to accept and manage long-term agreements. Forestry in general, but managing for sustainability and for carbon credits particularly, require long-term planning in accordance with performance standards. The forestry expertise, record keeping, staffing and practices that certified landowners have in-house enable them to conduct and implement these long-term plans, but also enable them to take on the operations and management of a carbon credit project with less additional effort, time, and expense.

Landowner Limitations

There are some characteristics of forest landowner organizations that may make them less likely to participate in carbon credit programs. Landowners who manage their lands extensively and intensively, or who maintain their forests with stocking levels that are comparable to the regional average, are less likely to have sufficiently large areas with stocking levels that exceed common practice to be good candidates for a carbon credit project. The forestland is less likely to earn enough credits to cover the costs of project development, operations and maintenance, and reversal risk.

Ownerships with many shareholders (particularly family holdings) may resist carbon credit programs due to their relatively complex decision making structure, and because they may prefer to distribute income immediately rather than set aside a portion of the proceeds from carbon credits to cover long-term project operations and maintenance costs. Owners who are institutionally, financially or culturally averse to risk, regulation, or long-term agreements are also likely to find carbon credit programs unpalatable.

Programmatic Constraints

Maine's SFI Program Participants who responded to the survey for this paper mentioned several aspects of the ARB program that had prevented them from applying for carbon credits. The biggest challenges for them were the costs and risks of a carbon project over 100 years, weighed against the current markets for wood and relative ease of subdividing and selling land.

Maine landowners and managers are particularly concerned about the lack of clarity regarding how reversals from presalvage harvests will be handled by the ARB. Spruce budworm infestations can be expected to occur two or three times over the minimum 100-year life of a carbon project, and if credits must be repaid for reversals from presalvage harvests, depending on the magnitude and intensity of the outbreak, it could pose a considerable risk to the viability of a project.

The limitations on clearcutting and shelterwood harvests are a lesser deterrence for landowners, but a deterrence nonetheless. In general, the "natural forest management" proscriptions on even-age management in the Forest Protocol are misaligned with management practices of most large commercial ownerships in Maine. Even-age management is a common tool in the state, and Maine forestry regulations already restrict clearcutting. At the same time, millions of acres in Maine are managed to sustainability standards. It is not clear that the Forestry Protocol adds anything of value to the offset carbon credit market beyond the state regulations and sustainability certification rules, and for landowners, it only represents another layer of regulation, requiring additional training, monitoring and reporting.

For certified landowners whose lands are encumbered by working forest conservation easements funded by Land for Maine's Future bonds, obtaining carbon credits for use in a compliance program such as the California ARB cap-and-trade program is likely prohibited. The precise easement language has changed over time and it is not clear whether every iteration applies to carbon credit programs, but language in the current easement template specifically prohibits the landowners from obtaining carbon credits to offset "development" elsewhere. Regardless of the language, the effect is the same: some landowners may have not pursued carbon credits due to the actual or perceived legal obstacle.

Programmatic Opportunities

Some uncertainties in the regulatory language and the carbon credit market argue for entering into carbon agreements sooner rather than later. Because the ARB program is currently set to expire in 2020, there is a

narrow window within which to obtain credits under the current regime. It is not clear whether or when new regulations will be written to support California's stated commitment to reduce greenhouse gases until the year 2030. The current program may represent the proverbial bird in the hand.

As the benchmark for additionality is updated through the Forest Inventory Analysis, the "common practice" average mtCO₂e/acre may increase. This possibility would make it harder to demonstrate additionality over time and creates an incentive to enter the market before the next update.

Landowners' cost-benefit analyses may shift in favor of carbon credits with the currently depressed prices for wood, demonstrating the value of having an additional source of forest revenue from carbon. Credit prices could also increase in the near future. Finally, costs could be somewhat reduced by conducting certification and carbon audits simultaneously.

Considerations for Landowners Contemplating Carbon Credits

- Carbon credit programs reward past conservative forest management by monetizing existing carbon stock levels that are above the average for the surrounding ecoregion. Carbon credits should not be considered a substitute for harvest income, but rather a diversification of income from forest resources. Land managers who currently manage their forests in alignment with SFI, FSC or ATFS certification standards and are generally conservative in their forest management approach should not expect to significantly change their management practices in order to have a viable carbon credit project.
- Areas that a landowner voluntarily manages under reduced or light harvest protocols including riparian zones, aesthetic buffers, and hard-to-access stands can make significant contributions to an ownership's overall carbon project performance. Overall, the challenge to creating an economically viable project is identifying projects where maintaining high carbon stocking does not conflict with, but rather complements, the landowner's current and planned management approach.
- All economically viable projects must have sufficient carbon across the project area to cover the costs of project design, operation and maintenance. Economic viability is a function of:
 - Acreage, site productivity, and growing season;
 - Management objectives;
 - Project onsite carbon density per acre in relation to the applicable ARB common practice;
 - Project development and ongoing operations and maintenance costs;
 - Credit prices; and
 - Fiber markets.
- For projects that get credits for both existing carbon stocks and growth, generally project revenue is front-loaded with 75-90% of project revenue credited for the existing stocks over common practice at project initiation. Growth-only projects are generally not financially viable.
- Forest landowners who are actively maintaining higher stocking levels and intend to do so over the long term are more likely candidates for carbon credit programs.
- While Maine currently has one carbon project area as small as 552 acres, most landowners will find that the high costs of a carbon project can only be offset by credits on an ownership of thousands of acres.

- SFI Program Participants and lands certified under other sustainability certification programs meet a key eligibility threshold for carbon credit programs, but more importantly, have the resources and expertise to manage a carbon project and can realize some cost savings by performing monitoring, inventories, and annual reporting in-house.
- Organizations with many shareholders may find it more difficult to commit to a 100-year carbon project than those with one or a few decision-makers due to the reduced flexibility in forest management and limitations the shareholders may place on the use of the credit proceeds.
- Any organization that is culturally averse to regulation and long-term agreements will find it difficult to commit to encumbering land with a carbon agreement.
- Organizations that intend to hold their land over the long-term (e.g., conservation groups and family ownerships) must be assured the carbon credits will more than offset the associated costs over the entire 100-year life of the project.
- TIMOs and REITs that are likely to sell land in less than 100 years and can pass the annual revenues and long-term project operations and maintenance costs on to the new owners also need to consider the impacts of the carbon agreement on their exit strategy — including potentially constrained markets and discounted land sales prices. REIT-owned lands outside of Maine under carbon agreements have been sold, but it is not clear to what extent the carbon agreement affected the sale price. Furthermore, given the variability of the future price of carbon credits and individual project costs, it would be difficult to predict the future effect of carbon agreements on land prices.
- Clearcuts and presalvage harvests are sometimes warranted, but risk financial penalties for reversals when harvest volumes exceed growth.
- The Land for Maine’s Future Working Forest Conservation Easement language currently prohibits enrolling lands that are conserved using LMF funds in carbon credit programs. Unless the state of Maine changes the terms of the working forest easement template, landowners interested in both working forest easements and carbon credit programs will have to choose one over the other.

Opportunities to Increase Enrollment in Carbon Offset Programs

The ARB regulations are in effect until 2020 and allow regulated entities to obtain offset credits through November 1, 2021. While the California legislature has committed to a further reduction of statewide greenhouse gas emissions to 2030, the cap-and-trade and offset programs have not yet been renewed and the program’s continuation is still being debated.

Quebec has linked their forestry offset program with California’s so that Canadian landowners can obtain credits in the California market, and Ontario is in the process of doing the same¹⁵. While the Regional Greenhouse Gas Initiative (RGGI, covering the New England states, Delaware, Maryland and New York) has the regulations in place to accept forestry offsets projects and has adopted California’s forest offset protocols, so far, no one has sought carbon credits for forestry projects in the RGGI market, and so a price for forestry offset credits has not

¹⁵ British Columbia and Manitoba are also in the process of developing carbon markets that will “harmonize” with California’s. However, these markets are not yet active.

been set. The current program may represent the proverbial bird in the hand (though the voluntary market will remain as an opportunity for landowners).

There may be opportunities to influence the development of the ARB's and Canadian provinces' forestry offset credit programs to facilitate the enrollment of lands certified as sustainably managed. The following regulatory changes would be a step in that direction.

Natural Forest Management

The natural forest management practices required in the Forest Protocol are, to some extent, redundant for Maine lands managed to SFI sustainability standards. Certification programs already prescribe forest management practices that maintain some level of ecological co-benefits, although there is a debate as to relative appropriateness of the ARB and SFI standards. ARB should give consideration to state regulations and certification requirements that meet the intent of the Forest Protocol requirements, and future revisions to the ARB protocol should examine the extent to which the protocol's requirements are appropriate for ecosystems outside of California.

Presalvage Harvests

Presalvage harvesting is a critical tool for land managers who wish to minimize the fiscal impacts of infestations of insects and pathogens. This paper has discussed the risk of penalties posed by presalvage harvests of spruce budworm-infested stands, but there are other insects and diseases that landowners may manage through presalvage harvests. These types of harvests enable the landowner to realize the value of the wood before the trees die and potentially control the spread of the insect or pathogen. Only presalvage harvests that remove more volume than growth since the last annual report risk penalties for an intentional reversal, but landscape-scale infestations may warrant such harvests, and landowners should not be penalized for prudent management. The Forestry Protocol should provide a way to conduct some reasonable level of presalvage operations as a planned harvest and/or an unintentional reversal.

Auditing Efficiencies

While the processes for sustainability certification audits and carbon credit programs' verification audits differ, their frequency is very similar. Conducting both audits simultaneously appears to be a simple way to reduce the time and associated costs of land managers' staff's assistance with the audits.

Working Forest Conservation Easement Language

"Carbon sequestration and carbon dioxide credit programs" are specifically prohibited under the language of Maine's current Land for Maine's Future working forest easement template. It is not clear whether the purpose of this prohibition is due to a concern that landowners would be "double-dipping" (receiving payments from both the LMF bond funds and the carbon market for the same environmental benefit), or because of a "leakage" concern (where the benefits from encumbering land with an LMF easement are undone to one degree or another by enabling environmental degradation elsewhere). Both concerns are unfounded. The ARB has regulations for Avoided Conversion (i.e., conservation easement) offset projects which preclude double dipping by only allowing landowners to obtain credits for carbon stocks above the level resulting from simple compliance with the terms of the easement. There is no "leakage" from ARB Improved Forest Management projects because these projects earn credits for sequestered carbon and are not used to mitigate or augment development elsewhere — the credits offset existing emissions; not additional emissions. Landowners with property under an LMF working forest conservation easement should not be precluded from earning credits for carbon sequestered on sustainably managed lands, as all ARB-approved projects are. Until the Working Forest

Easement language under the Land for Maine's Future Program is changed, lands covered by these easements will presumably be limited to the voluntary carbon credit market.

Credit Prices

For many landowners, the decision whether to enter the carbon credit market is strictly a matter of financial return and risk. Viable carbon projects are those where carbon represents a diversification of income from the forest rather than a substitution for harvest income. However, harvest income and carbon credits do compete with each other in terms of their relative risks and management demands. Obviously, the incentive for landowners to enroll land in carbon credit programs increases as carbon credit prices increase. Some Maine landowners have commented that, when wood markets are healthy, carbon credit prices would need to be in the \$20-\$30 per credit range to make the costs and risks of a carbon project worthwhile. As the carbon credit markets approach this price, many new forest offset projects may be registered.
